### Abstract

**Background:** The antioxidant properties of ethanolic root extract of pepper fruit (*Donnetia tripetala*), and its effect on lipid peroxidation of some fresh beef tissues during frozen storage were investigated.

**Materials and Methods:** The antioxidant parameters were assessed using standard methods, while malondialdehyde levels of different fresh beef tissue sections treated with the extract prior to freezing, were estimated in a colorimetric reaction with thiobarbituric acid.

**Results:** The H<sub>2</sub>O<sub>2</sub>-scavenging ability of the extract was similar to that of ascorbic acid, with a maximum scavenging power of 55.61 ± 4.98%, and an IC<sub>50</sub> value of 86 µg/ml. The extract exhibited a concentration-dependent ferric ion-reducing power, although this was significantly lower relative to that of the ascorbic acid (p < 0.05). The total phenolic content was 212.5 ± 0.002 mg/g, while the nitric oxide-scavenging ability was 64.33 ± 0.2% after 150 min. The capacity of the extract to inhibit lipid peroxidation in frozen heart muscle slices was significantly higher than that of vitamin C (p < 0.05), but comparable to vitamins C and E in frozen testes and kidney slices.

**Conclusion:** These results suggest that the root extract of *D. tripetala* is rich in antioxidants which can be applied to meat preservation during refrigerated storage.

**Keywords:** *Donnetia tripetala*, Root Extract, Antioxidants, lipid peroxidation, Beef

### Introduction

Studies on biochemical basis for therapeutic properties of medicinal plants have become popular in recent times. These investigations aim at unraveling the scientific basis for various claims of traditional healers on the therapeutic effects of roots and herbs. *Denntia tripetala* G. Baker (family *Annonaceae*), is a well-known forest and spicy medicinal plant found in the rainforest zone of Africa (Ejechi et al. 1999; Okwu and Morah, 2004). The fruits of the tree plant, popularly called pepper fruit in Nigeria, are edible and have a fiery but spicy taste. In some Nigerian communities, the fruits are used for the treatment of cough, fever and toothache (Adebayo et al. 2010). It also serves as mild stimulant, source of some vitamins, appetite stimulant, mouth wash and anti-pyretic (Gill, 1992; Enwere, 1998; Keay, 1989). The fruits are rich in antioxidants. A survey of existing literature shows that pepper fruits contain *Dennettia* essential oils and phenolic acids (Anyaele and Amusan, 2003) as well as alkaloids (Rossanan et al. 2003). Vanillin, dennettine (a new 2, 6-dimethoxy-chrome), argentinine and uvariopsine have been isolated from *D. tripetala* (Janview et al. 2002). The antioxidant properties of either the ripe and unripe fruits of *D. tripetala* have been reported (Adebayo et al. 2010; Oboh and Rocha, 2007). In addition, the fruit extracts have been shown to be active antifungal agents (Adedire and Akinkurolere, 2005).

Although the roots of *D. tripetala* are used ethno-medicinally for the treatment of cough, inflammation, and as vitamin supplement (Iwu, 1993), scientific investigations have so far focused mainly on the edible fruits. Thus not much is known about phytochemical composition of the roots and their antioxidant properties. The present study was therefore carried out to determine the phytochemical composition and the antioxidant potential of roots of *D. tripetala*.

### Material and Methods

#### Collection of plant material

Fresh sample of *D. tripetala* roots were obtained from Utteh Village, behind Ugbowo Campus of the University of Benin, Benin City, Nigeria. The identification and authentication of the plant, was done by Dr.O. Osawaru, of the Department of Plant Biology & Biotechnology, University of Benin.

#### Preparation of plant extract

The roots of *D. tripetala* (voucher No. 15356) were washed with distilled water and chopped into small pieces using a table knife. The pieces were then sun-dried and ground to powder in a grinder. 2kg of the powdered sample was suspended in 5L of 98% (v/v) ethanol for 24 hrs. Thereafter, the suspension was filtered through a clean piece of cheese cloth. The resultant ethanolic extract was concentrated in a rotary evaporator at 40°C. Using the dry extract, a stock concentration of 1,000 µg/ml was prepared in methanol. From the stock solution, different concentrations viz. 10, 20, 40, 60, 80 and 100 µg/ml were prepared in methanol and used for the antioxidant studies.

#### Phytochemical screening

The extract was screened for presence of alkaloids, saponins, tannins and flavonoids using the colorimetric methods outlined in Trease and Evans (1989).

<http://dx.doi.org/10.4314/ajtcam.v11i3.31>

### Determination of Hydrogen Peroxide Scavenging Capacity

The hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)-scavenging activity of the extract was determined by the method of {Srinivasan et al. 2007}. A solution of hydrogen peroxide (20 mM), was prepared in phosphate buffered saline (pH 7.4). Different concentrations of plant extract and standard ascorbic acid solution viz: 10, 20, 40, 60, 80 and 100 µg/ml in methanol (1 ml), were separately added to H<sub>2</sub>O<sub>2</sub> solution (2 ml), and mixed. Each tube was allowed to stand for 10 min after which absorbance at 230 nm was read against a blank solution containing phosphate buffer in place of H<sub>2</sub>O<sub>2</sub>. The percentage inhibition activity was calculated as follows:

$$\% \text{ inhibition} = [(A_0 - A_1)/A_0] \times 100,$$

Where A<sub>0</sub> is the absorbance of the control, and

A<sub>1</sub> is the absorbance of extract/standard.

The antioxidant activity of the extract was expressed as IC<sub>50</sub>. All the tests were performed in triplicate determination.

### Determination of ferric reducing power

The method described by Kumaran and Karunakaran (2007) was employed. Different concentrations of plant extract and standard ascorbic acid solution viz. 10, 20, 40, 60, 80 and 100 µg/mL in 1 mL of methanol were mixed with 0.2M phosphate buffer (2.5 mL, pH 6.6) and potassium ferricyanide [K<sub>3</sub>Fe(CN)<sub>6</sub>] (2.5 mL, 1%). The mixture was incubated at 50° C for 20 min. A portion (2.5 mL), of trichloroacetic acid (10%), was added to the mixture, which was then centrifuged at 3,000 g for 10 min at room temperature. The upper layer of solution (2.5 mL), was mixed with distilled water (2.5 mL), and 0.5 mL of 0.1% FeCl<sub>3</sub> solution. The absorbance, which reflects increase in reducing power, was measured at 700 nm. All the tests were performed in triplicate.

### Determination of Nitric Oxide (NO) scavenging activity

The NO scavenging activity of the extract was determined by the method of Daljit and Priyanka (2010). An aliquot (6 mL), of 5 mM sodium nitroprusside solution was mixed with 6 ml of extract and incubated at 25°C for two and half hours. 0.5 mL of the reaction mixture was removed at 30 min intervals, and mixed with an equal 0.5 mL of Griess reagent (1 % sulphanilamide, 2 % phosphoric acid, and 0.1 % naphthylethylene diamine dihydrochloride). The absorbance of the mixture was then read at 546 nm and compared with absorbance of 1 mg/mL standard solution (sodium nitrite), treated in the same way with Griess reagent.

### Determination of Total Phenolic Content (TPC)

The total polyphenolic content was determined colorimetrically using the Folin-Ciocalteu (FC), method of Daljit and Priyanka, 2010, with some modifications. Test sample (0.5 mL), was mixed with 0.2 mL of FC reagent and allowed to stand for 10 min. Then 0.6 mL of 20 % sodium carbonate was added with mixing, and the reaction mixture was incubated at 40°C for 30 min. before absorbance was measured at 765 nm. The polyphenolic contents were expressed as gallic acid equivalents. The determination was carried out in triplicates.

### Determination of Ascorbic acid

Ascorbic acid was determined using dinitrophenylhydrazine (DNPH), as described previously (Omaye *et al.* 1979). To each 1.5 mL of 6 % trichloroacetic acid (TCA), was added 0.5 mL of sample and the mixture centrifuged at 3500 g for 20 min. 0.5 mL of the supernatant was then added to 0.5 mL of DNPH reagent (2 % DNPH and 4 % thiourea in 9 M sulphuric acid). The solution was incubated for 3 hrs at room temperature, followed by the addition of 2.5 mL of 85 % H<sub>2</sub>SO<sub>4</sub>. Absorbance was read at 530 nm after 30 minutes. The assay was done in triplicates, and ascorbic acid content was calculated using the relation:

$$[\text{OD of test}/\text{OD of standard}] \times \text{concentration of standard}$$

Values were expressed in µg/g of extract.

### Determination of Vitamin E

Vitamin E was assayed by the method of Desai (1984). It was first extracted by the addition of 1.6 mL ethanol and 2.0 mL petroleum ether to 0.5 mL of sample. The mixture was stirred and allowed to stand for 10 min at room temperature. It was then clarified by centrifugation, and the supernatant obtained was evaporated to dryness. To the residue, 0.2 mL of 0.2 % 2, 2'-dipyridyl and 0.2 mL of 0.5 % ferric chloride were added and the mixture was kept in the dark for 5 mins. Thereafter 4 mL of butanol was added, and the absorbance of the resultant intense red colored layer was read at 520 nm. The vitamin E content was extrapolated from a standard curve in which serial dilutions of vitamin E were similarly treated as extract. Assays in extract were done in triplicate and results were expressed in mg/g of extract.

### Determination of Inhibitory Capacity of Extract on Lipid Peroxidation

This was measured against vitamin C and vitamin E with proven capacities as antioxidants and inhibitors of lipid peroxidation (Padayatty *et al.* 2003). Different organs - liver, testis, kidney, heart and muscle from a freshly slaughtered cow were obtained from an abattoir in Benin City, Edo State, Nigeria. The samples were transported to our laboratory in ice packs, and used immediately on arrival. 1 g portions of each sample were separately placed in 50 mL of each of the following solutions: 5 % solution of *D. tripetala* root extract, 5 % ascorbic acid, 5% vitamin E, and distilled water. The samples were kept frozen at 4°C in a deep freezer, and analyzed for malondialdehyde (MDA), levels at 48 hour-intervals for 35 days. MDA was determined colorimetrically using thiobarbituric acid (TBA), as described by Okolie et al. (2009). In essence, 1 g of the chilled tissue sample was homogenized with 100 mL of physiological saline for 15 min. The homogenate was centrifuged at 8000 g for 5 min. 1 mL of the supernatant was then added to 2.0 mL of TCA-TBA -HCl reagent (15 % TCA, 0.375 % TBA, 0.25 M HCl), and the solution was mixed thoroughly and placed in a boiling water bath for 15 min. On cooling, the protein precipitate was removed by centrifugation at 10,000 g for 5 min and the

<http://dx.doi.org/10.4314/ajtcam.v11i3.31>

absorbance of the clear, pink supernatant fraction was read at 535 nm against reagent blank. MDA values were calculated from the molar extinction coefficient and expressed as  $\mu\text{mole/g}$  fresh weight.

### Statistics

All assays were performed in triplicates, and results expressed as Mean  $\pm$  SD. Where appropriate, analysis of variance, ANOVA was used for determination of statistical differences between samples. P values  $< 0.05$  were taken as significant.

### Results and Discussion

The biochemical basis for medicinal properties of plants has continued to engage the attention of researchers. In these investigations, antioxidant parameters are frequently focused on. This is informed by the fact that the pathogenesis of many human diseases is traceable to imbalance between pro-oxidants and anti-oxidants (Rosen et al. 2001; Poulsen, 2005; Rahman, 2005; Paravicini et al. 2008; Zhang et al. 2009). Several studies have consistently reported that the medicinal properties of plants are largely attributable to their phytochemical antioxidant contents (Choo and Yong, 2011; Kim et al. 2007). Table 1 shows results of qualitative analysis of phytochemical composition of the ethanolic root extract of *D. tripetala*. The extract contains alkaloids, flavonoids, tannins and saponins. The levels of vitamins C and E, as well as the total phenolic content of the extract are shown in Table 3. The extract is rich in polyphenolic and vitamin E, but the level of vitamin C is very low. The total phenolic content value of 212 mg gallic acid equivalent/g obtained for the root extract of *D. tripetala* in this study is quite higher than values of 1.4 and 1.0 mg/g reported for the ripe and unripe fruits of the plant respectively (Adebayo et al. 2010). It is also higher than the values of total phenols reported for ripe and unripe fruits of *Capsicum pubescens* (Oboh and Rocha, 2007). This shows that the roots of *D. tripetala* which are often neglected may be of greater medicinal value than the fruits. Phenolic compounds act as antioxidants through mechanisms which include donation of protons, quenching of singlet oxygen and chelating of metals (Rice-Evans et al., 1996; Heim et al. 2004; Abdel-Hameed, 2009; Abdel-Hameed, 2012). Figure 1 depicts the  $\text{H}_2\text{O}_2$  - scavenging capacity of the extract relative to that of standard ascorbate. The extract showed concentration-dependent  $\text{H}_2\text{O}_2$  - scavenging capacity which was comparable to that of the ascorbic acid, with an  $\text{IC}_{50}$  value of 86.79  $\mu\text{g/ml}$ .

**Table 1:** qualitative phytochemical composition of root extract of *D. tripetala*

Phytochemical class	Status

Indole alkaloids	+ve
Tropane alkaloids	+ve
Alkaloids	+ve
Tannins	+ve
Saponins	+ve
Flavonoids	+ve

+ve = present

**Figure 1:**  $\text{H}_2\text{O}_2$  -scavenging activity of *D. tripetala* root extract relative to ascorbic acid

**Figure 2:** Ferric reducing power of *D. tripetala* extract and ascorbic acid

Thus, the high levels of these polyphenols in the root extract of *D. tripetala* may account for the fact that the  $H_2O_2$  scavenging activity of the extract was comparable to that of standard ascorbic acid. In addition, the vitamin E content of *D. tripetala* root extract ( $2.67 \pm 0.02$  mg/g) was very high, considering the notion that roots, with a few exceptions are generally poor sources of the vitamin. However the root content of vitamin C ( $0.14$  µg/g), was much lower than that reported for the fruits (Adebayo et al. 2010). This is not surprising, since fruits are generally better sources of vitamin C than roots. Figure 2 shows the ferric ion reducing potential of the ethanolic root extract of *D. tripetala*. The ability of the extract to reduce ferric ions was concentration-dependent, but it was significantly lower than that of standard ascorbic acid ( $P < 0.05$ ). The NO-scavenging activity of the extract is shown on Table 2. This was time-dependent, with a maximum value of 64 % after 150 min. Thus, the various antioxidant properties exhibited by the root extract such as ferric ion reducing, as well as NO- and  $H_2O_2$ - scavenging activities may be due mainly to vitamin E and polyphenols. Tables' 4 - 8 show results obtained in the comparison of the capacity of the extract to inhibit lipid peroxidation in some beef tissue slices with those of vitamin C, vitamin E and distilled water. The ability of the extract to inhibit lipid peroxidation (i.e. decrease MDA levels) in frozen heart muscle slices within 10 days was significantly higher than that of vitamin C ( $p < 0.05$ ; Table 7), but comparable to those of vitamin C and vitamin E in frozen testes and kidney slices (Table 6 and Table 8 respectively). However, the ability of the extract to inhibit MDA formation was significantly lower in beef liver and muscle when compared with either vitamin C or vitamin E (Table 4 and Table 5 respectively). Tissues frozen in water medium had the highest MDA in virtually all cases.

**Table 2:** vitamin C, vitamin E and total phenolic content (tpc) of *D. tripetala* oots

Compounds	Concentration
Vitamin C	$0.14 \pm 0.020$ µg/g
Vitamin E	$2.67 \pm 0.002$ mg/g
Total Phenolic Content (TPC)	$212.50 \pm 0.002$ mg gallic acid/g

(Values are mean  $\pm$ SD of three determinations for each parameter)

<http://dx.doi.org/10.4314/ajtcam.v11i3.31>

The ability of the extract to inhibit lipid peroxidation in some frozen beef tissue slices is particularly interesting, and further confirms its significant antioxidant potential. Although the extract was not as effective as the antioxidant vitamins in arresting MDA formation in beef muscle and liver, it was nonetheless better than vitamin C in inhibiting lipid peroxidation in heart muscle slices, and exhibited the same level of protection as vitamins C and E with respect to kidney and testes. This shows that the extract may be of beneficial application in refrigerated storage of meat and meat products in homes and cold storage facilities. This is based on the fact that lipid peroxidation was regarded as a major source of quality deterioration, not only in meat and meat products but also in fish and fish products. The disparity with respect to ability of the extract to inhibit lipid peroxidation in liver and muscle is consistent with the finding that the susceptibility to lipid peroxidation was a function of muscle type and anatomical location (Rhee and Ziprin, 2000; Rhee et al. 1996). Aside from the production of undesirable changes in flavor and loss of food quality, lipid peroxidation increases the level MDA in foods. Studies have revealed that MDA is one of the most abundant lipid peroxidation cytotoxins formed in foods, especially in meat (Stocker and Keane, 2005; Gorelick et al. 2007). Earlier reports on the mutagenic and carcinogenic potentials of MDA (Shamberger et al. 1970; Hadley and Drager, 1989), have since led to increased interest in its implication for human health. Following ingestion of peroxidised foods, humans and lower animals have been shown to excrete increased amounts of MDA in the urine (Hadley and Drager, 1989). Indeed it is now known that MDA can be absorbed from tainted foods when these foods are ingested (Gopaul et al. 2000; Giron-Calle et al. 2002). MDA is genotoxic, reacting with DNA to form highly mutagenic adducts in human cells (Riggins et al. 2001; Del-Rio et al. 2005). Consequently lipid peroxidation in foods is deleterious to human health. Thus the ability of the root extract of *D. tripetala* to inhibit lipid peroxidation in the frozen beef tissues is highly desirable, especially since it has been demonstrated that lipid peroxidation also occurs even during refrigerated storage of meat and fish (Okolie et al. 2009; Okolie et al. 2013).

### Conclusion

This study has for the first time, demonstrated experimental evidence for antioxidant properties of roots of *D. tripetala*. These properties can be ascribed to the high levels of antioxidant phytochemicals present in the root. These findings are considered crucial, for they may provide a biochemical basis for some of the medicinal uses of the roots of *D. tripetala*.
