### ABSTRACT

Since 1990, UNDP has considered GNI per capita as a microeconomic variable that yields decreasing marginal material welfare in the calculation of HDI. Consequently, international inequality of development is significantly and unrealistically reduced. In this paper we support that GNI per capita is a macroeconomic variable with increasing marginal material welfare at the national level. We then propose an alternative method of transforming GDP per capita into material welfare. We use this formula on HDI data of the year 2016. We obtained a new HDI\_2016 for all UN countries; this new HDI\_2016 is associated with a new ranking of countries and with a significant and realistic increase in international inequality of development measure.

**Key words:** GNI per capita; Increasing; marginal utility; Human Development Index

**JEL CLASSIFICATION:** O15

## UTILITÉ MARGINALE CROISSANTE DU PNB PAR TÊTE ET INDICATEUR DU DÉVELOPPEMENT HUMAIN (IDH)

### RÉSUMÉ

Depuis 1990, le PNUD considère le PNB par tête, dans le calcul de l'IDH, comme une variable microéconomique dont l'utilité marginale est décroissante. Ceci a pour conséquence de réduire anormalement l'inégalité de niveaux de développement perçu entre nations. Dans cet article, nous soutenons que le PIB par tête est un agrégat macroéconomique dont l'utilité marginale pour les citoyens d'un pays est plutôt croissante. Nous proposons alors une formule alternative de calcul de la composante bien-être matériel de l'IDH. Une application sur les données de l'IDH de l'année 2016 nous donne un nouvel IDH\_2016 pour tous les pays considérés par le PNUD. Ce nouveau IDH\_2016 modifie significativement le classement des pays et ramène l'inégalité internationale de niveau de développement à un niveau plus réaliste.

**MOTS CLÉS :** PNB par tête; bien-être matériel croissant; Indice du Développement Humain

## زيادة العائدات إلى الدخل القومي الإجمالي للفرد ومؤشر التنمية البشرية

### ملخص

يعد برنامج الأمم المتحدة الإنمائي نصيب الفرد من الدخل القومي الإجمالي منذ عام 1990 متغيراً اقتصادياً جزئياً يؤدي إلى انخفاض الرفاهية المادية الهامشية في حساب دليل التنمية البشرية، مما يؤدي وبشكل لافت وغير واقعي إلى تقليص مستويات التنمية بين الدول.

نؤيد في هذه الورقة البحثية أن نصيب الفرد من الدخل القومي الإجمالي هو متغير اقتصادي كلي مع زيادة الرفاهية المادية الهامشية على المستوى الوطني، ومنه نقترح صيغة بديلة لتحويل نصيب الفرد من الدخل القومي الإجمالي إلى رفاهية مادية. إن استخدام هذه الصيغة على بيانات مؤشر التنمية البشرية لعام 2016 سيظهر مؤشر تنمية جديد لعام 2016 لكل البلدان التي يمسها برنامج الأمم المتحدة للتنمية (PNUD). يعدل هذا المؤشر الجيد وبشكل ملحوظ ترتيب الدول ويجعل عدم المساواة لمستوى التنمية الدولية أكثر واقعية.

كلمات مفتاحية: الدخل القومي الإجمالي للفرد الواحد، المنفعة المادي، مؤشر التنمية البشرية

## INTRODUCTION

Since the end of the 1960s, economists have been looking for an objective<sup>2</sup>, synthetic, relevant and operational indicator of the development of Nations. McGranahan (1971) proposed the General Development Index (GDI), but it failed to consider the economic aspects of life. In 1979, Morris D. Morris proposed the Physical Quality of Life Index (PQLI), which considers nine economic and nine social variables. But these numerous variables are sometimes negatively correlated, so the PQLI cannot be considered as relevant. In 1990, the United Nations Development Program (UNDP) proposed the Human Development Index (HDI), and since then, a *World Human Development Report* is published on annual basis.

The HDI is a synthetic development indicator, taking into consideration both economic and social aspects of life. On the economic aspect, material welfare is obtained through a transformation of the countries' GDP per capita. On the social aspect, two variables are considered: education, initially represented by the adult literacy rate; and health represented by life expectancy at birth. The HDI is one of the most popular development indicators, as many political authorities and researchers refer to it. Through this paper we want to contribute to the debate for the amelioration of this indicator. The amelioration we propose aims at reducing the difference of inequality between development indicators, especially between HDI and the revenue per capita, as pointed out by McGillivray and Pillarisetti (2004). These authors emphasized the necessity of reducing the gap in the difference between Purchasing Power Parity (PPP) revenue per capita and the HDI. Their results showed that the importance of this difference depends on the method of transforming PPP revenue per capita into a material welfare measure.

---

<sup>2</sup> Concurrently, some organisations provide statistics and measures of subjective happiness of countries' citizens: the Gallup World Pool (GWP), the World Values Survey (WVS), the European Social Survey (ESS) and, since 2012, the Centre for Economic Performance of the London School of Economics and Political Science publishes annually a World Happiness Report.

Indeed, since 1990, HDI has faced external and internal critics (Kovacevic, 2011, Ghislandi and al., 2019). Some of these tackle representativeness of included variables (Dasgupta and Weale, 1992, Tinbergen, 1974, Coomb and Manzoor, 1974, Cotlear, 1990, Allen and Kelly, 1991, Hopkins, 1991, Dasgupta, 1993, Dasgupta, 1994, Trabold-Nubler, 1994; Sudhir, 2018). A second category of critics points out the problem of inter-temporal comparison of HDI (Sudhir and Sen, 1992, Anand and Sen, 2000, Saha, 2005, 2009, Ziogianis and al., 2019); a third category tackles the problem of overall coherence of variables (Cornia, 1990, McGillivray, 1991, Noorbakhsh, 1997, 1998, Cahill, 2000, Ravallion, 2012; Sayed and al., 2018). A last category of critics deals with the mathematical treatment of variables (Bhanojirao, 1991, Allen and Kelly, 1991, Sudhir and Sen, 2000, Cahill, 2002, Leon-Castro and al., 2021) in general; in particular, the treatment of Gross Domestic Product (GDP) per capita: the method of transforming it into a material welfare measure has been criticised. Consequently, this method has changed many times and still is to be improved.

In 1990, UNDP considered that the marginal utility of GDP per capita decreases and becomes null after a certain threshold ( $Y^*$ ). The economic welfare measure is then obtained using a logarithmic transformation of GDP per capita.<sup>3</sup> So the material welfare ( $W$ ) for a country  $j$  is given as:

$$\begin{aligned} W(Y_j) &= \text{Log}(Y_j) && \text{if } Y_j < Y^* \\ &= \text{Log}(Y^*) && \text{if } Y_j \geq Y^* \end{aligned} \quad (1)$$

In 1991, after violent critics, UNDP accepts on the one hand that below  $Y^*$  there is no decreasing marginal utility and, on the other hand, that beyond  $Y^*$ , additional units of  $Y^*$  yield decreasing marginal utility. So the following Atkinson (1983) formula is used.

---

<sup>3</sup>  $Y^*$  is considered equal to the arithmetic mean of poverty lines in nine rich countries (Federal Republic of Germany, Australia, Canada, USA, Norway, Netherlands, Great Britain, Sweden, and Switzerland), in Purchasing Power Parity (PPP) Dollar.

$$\begin{aligned}
 W(Y_j) &= Y_j && \text{if } Y_j \leq Y^* \\
 &= Y^* + 2(Y_j - Y^*)^{\frac{1}{2}} && \text{if } Y^* < Y_j \leq 2Y^* \\
 &= Y^* + 2(Y^*)^{\frac{1}{2}} + 3(Y^*)^{\frac{1}{3}} + \dots + n[Y_j - (n-1)Y^*]^{\frac{1}{n}} \\
 &\text{if } (n-1)Y^* < Y_j < nY^*
 \end{aligned} \tag{2}$$

In 1999, UNDP considers on the one hand that GDP per capita always faces decreasing marginal utility, and, on the other hand abandons the idea of an international poverty line. So the following method is adopted and used since 1999.

$$W(Y_j) = \text{Log}(Y_j) \quad \forall Y_j \tag{3}$$

As we can see, there has been an important instability in the method of transforming national revenue per capita into a material welfare measure. The reason is the fact that UNDP seems to be confused as the status of GDP per capita is concerned. Is it a microeconomic or a macroeconomic variable? In this article we try to support that GDP per capita is a macroeconomic variable and to propose a more suitable method that can give amore pertinent HDI, with an application on the HDI\_2016.

The article is composed of three sections. Section 1 presents the theoretical confusion of the UNDP on the status of GDP per capita and exposes our thesis. Section 2 presents our method of treating GDP per capita, with application on HDI\_2016. Section 3 gives a comparison of our results with the UNDP's HDI\_2016.

#### 1- THE GDP PER CAPITA: A MICROECONOMIC OR A MACROECONOMIC VARIABLE?

Is GNI/GDP per capita a microeconomic variable that should exhibit decreasing marginal utility or a macroeconomic variable that can exhibit increasing returns? We first present elements that illustrate the UNDP's confusion about this question, and secondly we present arguments supporting that it should be considered as a macroeconomic variable.

### 1.1-The UNDP position is confused

In the *Human Development Report 1993 (HDR\_1993)*, on page 105, it is written: *“Life expectancy at birth is an average for an entire group (nation, region, ethnic group), however, not the characteristic property of an individual, as income can be”*. This means clearly that according to UNDP experts, GNI per capita is a microeconomic variable<sup>4</sup> with decreasing marginal utility. This decreasing marginal utility of GNI per capita is the main theoretical foundation of all the methods adopted since 1990. On page 107 of this same HDR\_1993, UNDP experts explain why before  $Y^*$ , marginal utility of GNI per capita, considered as a microeconomic variable, is constant, why it is decreasing after, and why an Atkinson formula should be used: *“if we consider the poverty level as the minimal cost of providing for the essential choices, it is difficult to argue that extra income within that range is somehow less effective in increasing well-being...”*.

But, surprisingly in the same HDR\_1993, page 107, we find arguments supporting the macroeconomic status of GNI per capita: *“Our measure is per capita income, which is a group average rather than personal income”*. A group average means a macroeconomic variable, and, as such, GNI per capita should face increasing marginal utility according to UNDP on the same page: *“..... There is no utility calculable until a minimum level of consumption is achieved with respect to each good in a set of goods. It is only extra consumption - above subsistence- that yields utility”<sup>5</sup>*.

So for UNDP experts, it is not so clear whether GNI per capita is a microeconomic variable with decreasing marginal utility or a

---

<sup>4</sup> An important question arises: As UNDP has combined macroeconomic variables with a microeconomic one into a single development indicator, how have they avoided the consistency problem related to this kind of exercise?

<sup>5</sup> Here, UNDP cites Desai (1990). This citation means that marginal utility of GNI per capita, as a macroeconomic variable, should be rather increasing after  $Y^*$ . The poverty line ( $Y^*$ ) constitutes a kind of foundation on which consumers build their utility maximization process. Since one cannot build a house without foundation, UNDP experts support that we cannot calculate a consumer utility as long as  $Y^*$  is not reached.

macroeconomic one with increasing marginal utility. In the paragraph we present our arguments to support that GNI per capita should be considered as a macroeconomic variable with increasing marginal utility at the national level.

### 1.2- Arguments supporting the macroeconomic status of GNI per capita

We support that GNI per capita is a macroeconomic variable that faces increasing marginal material welfare at the national level. Indeed, in rich countries, government share less important financial resources from taxes on high revenues<sup>6</sup>. These resources are invested in "*public goods or goods provided by public authorities: environment, infrastructure (road network for example), electricity, transport and communication, epidemiological protection, etc* " (Anand and Sen, 1992). Better public goods and better social services are then provided. Better public goods and better social services increase the marginal utility of low personnel incomes.

This is why in rich countries, even poor individuals, as they receive good education and health services, consume good collective infrastructure, live in a clean environment, etc., live better live than poor individuals in poor countries. In these rich and developed countries, high revenues of rich individuals (the very large majority of the population is above the poverty line) help increase the marginal utility of low revenues of poor people. In poor countries on the contrary, rich individuals (a minority of the population) receive relatively poor education and poor health services, they consume relatively poor collective infrastructure, live in relatively poor environment, etc., because governments are relatively poor, and governments are poor because a large proportion of the population are poor. So in poor countries, rich people cannot live as well as their equivalents in rich countries. There is a negative influence of poor people on material welfare of rich people in poor countries, whereas in rich countries there is a positive influence of rich people on the material welfare of poor people. This idea has already been suggested

---

<sup>6</sup> In many countries today, rich or poor countries, taxation system is progressive, rich individuals pay more taxes, in proportion of their revenue, than poor individual.

by Roser (2013) who indicated that *'today's global inequality of opportunity means that what matters most for your living conditions is the good or bad luck of your place of birth'*<sup>7</sup>. A suitable transformation of GNI per capita into material welfare of the average citizen should then consider it as a macroeconomic variable that yields increasing marginal utility.

## 2- A MORE APPROPRIATE METHOD FOR THE TRANSFORMATION OF GNI PER CAPITA INTO A MATERIAL WELFARE MEASURE

### 2.1- Theoretical presentation of the method

We consider that under a certain threshold  $Y^*$ , GNI per capita yields constant marginal utility. Beyond  $Y^*$ , the first supplementary  $Y^*$  faces increasing marginal utility, the second one faces constant marginal utility, and above  $3Y^*$  it faces decreasing marginal utility. Our  $Y^*$  is not the international poverty line as for UNDP, but an international development line<sup>8</sup>. This international development line ( $Y^*$ ) is the average GNI per capita in upper middle income countries. In 2016, based on the World Bank data,  $Y^*=12,928.203$  PPP\$. The material welfare ( $W$ ) for country  $j$  whose GNI per capita is  $Y_j$  will then be computed as:

$$\begin{aligned}
 W(Y_j) &= Y_j \text{ if } Y_j \leq Y^* \\
 &= Y^* + (Y_j - Y^*)^2 \text{ if } Y^* < Y_j \leq 2Y^* \quad (4) \\
 &= Y^* + (Y^*)^2 + (Y_j - 2Y^*) \text{ if } 2Y^* < Y_j \leq 3Y^* \\
 &= Y^* + (Y^*)^2 + Y^* + \text{Log}(Y_j - 3Y^*) \text{ if } Y_j > 3Y^* \\
 &= 2Y^* + (Y^*)^2 + \text{Log}(Y_j - 3Y^*) \text{ if } Y_j > 3Y^*
 \end{aligned}$$

---

<sup>7</sup> Roser M.(2013) emphasized that *'for people's material prosperity, where you live isn't just more important than all your characteristics, it's more important than everything else put together.....you cannot get healthy and wealthy on your own—societies make progress, not individuals.....when everyone is sick, everyone is sick.....'*

<sup>8</sup> By using the international poverty line, UNDP considers the development of Nations simple as simple absence of poverty. We support that development is not simply the absence of poverty, and that development line is superior to the poverty line.

**2.2- Calculation of the new materiel welfare index**

We have applied this method on UNDP countries for the year 2016. Illustration in given below on the cases of Cameroon (GNI per capita =2,894.278 PPP\$) and Canada (GNI per capita=42,581.914 PPP\$).

Cameroon:  $W(Y) = 2,894.278$  as  $Y_{cam} < Y^*$

Canada:

$$W(Y) = Y^* + (Y^*)^2 + Y^* + \text{Log}(Y_j - 3Y^*) = 167,164,292.795$$

as  $3Y^* < Y_{can} < 4Y^*$

The maximum GNI per capita is that of Qatar,129,915.601 PPP\$, so the maximum economic welfare is  $W(Y_{max})=167,164,294.175$ . The minimum GNI per capita, as adopted by the UNDP, is 100 PPP\$, so the minimum economic welfare is  $W(Y_{min})=100$ . The income index for Cameroon and Canada are then:

For Cameroon:  $II = \frac{2,894.278 - 100}{167,164,294.175 - 100}$

For Canada:  $II = \frac{167,164,292.795 - 100}{167,164,294.175 - 100}$

Table 1 below presents the results for some countries, comparing this new income index with the UNDP’s one in 2016. As we can see, our formula increases the income index for rich countries and reduces it for poor countries, so increases the material welfare inequality across nations. This lager inequality is however closer to the reality than the one associated to the UNDP’s income index.

**Table 1.** Comparison of UNDP’s and our income indexes for some selected countries

Country	GNI per capita	UNDP's income index	New income index	Income index variation
Norway	67 614.353	0.984	1.000	0.016
Germany	44 999.647	0.923	1.000	0.077
Denmark	44 518.924	0.921	1.000	0.079
Singapore	78 162.324	1.000	1.000	0.000
United States	53 245.077	0.948	1.000	0.052

Japan	37 267.964	0.894	1.000	0.106
Korea (Republic of)	34 540.649	0.883	1.000	0.117
Italy	33 572.982	0.879	1.000	0.121
Qatar	129 915.601	1.000	1.000	0.000
United Arab Emirates	66 203.300	0.981	1.000	0.019
Kuwait	76 075.207	1.000	1.000	0.000
Panama	19 470.203	0.796	0.256	-0.540

Central African Republic	587.474	0.267	0.000	-0.267

Source : Our results

As we can see on the table, countries whose GNI per capita in superior to 2Y\* have a new income index approaching 1, while countries with lower GNI per capita register a decrease in their income index which tends to 0. The figure 1 in the appendix, containing all UNDP countries, is more illustrative, showing how income index variations are positive and important for rich countries, negative and important for middle income countries, negative but less important for poor countries.

### 3- NEW HDI, NEW COUNTRIES' RANKING AND NEW INTERNATIONAL INEQUALITY OF DEVELOPMENT

We have computed a new HDI\_2016 for all UNDP countries. Results show a significant difference with the UNDP's HDI\_2016 for

many countries, a significant change in the ranking of countries as well as a significant increase in international inequality.

### 3.1- The new HDI\_2016 and new ranking of countries

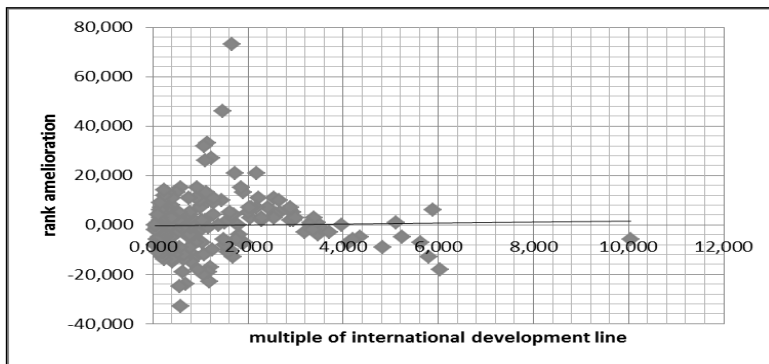

The new HDI\_2016 and the corresponding ranking of countries are presented in table 1 of the appendix and compared with those given in the *HDR\_2016*. We can see that for more developed countries there is not a significant difference between the new HDI\_2016 and the HDI\_2016, but for the less developed countries there is an important difference<sup>9</sup>. The variation of the ranking of countries is presented in table 2 of the appendix. This variation is important for some countries and less important for others. The figure 2 of the appendix shows the rank variation for all countries<sup>10</sup>. Our new method is also supposed to favour high revenue countries. For this hypothesis to be accepted, the modification of the ranking should be important for high income countries and less important for low income countries. The figure below suggests that this hypothesis should be rejected.

---

<sup>9</sup> As illustration: for Norway, New HDI\_2016=0.954 and the HDI\_2016=0.949; for Australia, new HDI\_2016 = 0.989 and HDI\_2016 = 0.939; for Canada, new HDI\_2016 = 0.948 and HDI\_2016 = 0.920, while for Congo D.R, new HDI\_2016 = 0.01 and HDI\_2016 = 0.435; for Guinea Bissau, new HDI\_2016 = 0.011 and HDI\_2016 = 0.424, for Burundi, new HDI\_2016 = 0.009 and HDI\_2016 = 0.404; for Chad, new HDI\_2016 = 0.012 and HDI\_2016 = 0.396; for Central African Republic, new HDI\_2016 = 0.008 and HDI\_2016 = 0.352.

<sup>10</sup> On the horizontal axis we put the ranking of countries according to UNDP\_2016, from the highest HDI (Norway) to the lowest (Central African Republic); on the vertical axis we put the difference with the new HDI\_2016 ranking (HDI\_2016 rank – new HDI\_2016 rank). When this difference is positive, the new rank for the country has deteriorated; when negative, the new rank for this country is better.

**Figure 1.** Rank modification in relation with countries' revenue

Source: From our results

On the horizontal axis, we put multiples of our international development line. Qatar has the highest revenue per capita (129,915.601 PPP\$), representing more than tin times our international development line. The revenue per capita in Canada is 42,581.914, more than three times the international development line. As we see, the large majority of countries are situated between zero and two times the international development line. On the vertical axis, we have the rank modification, ranging from -40 to 80. The figure shows no clear relation between revenue of countries and variation of their rank. So, our method has not favoured high revenue countries. Furthermore, we have drawn, using Least Square Ordinary (LSO) adjustment technics, a linear relation between the two variables, as it appears on the figure. This linear relation can be considered as not significantly increasing.

### 3.2. The new international inequality of development

Results also show that the international inequality has increased: the highest new HDI\_2016 is 0.989 and the lowest 0.008, the first represents more than 123 times the second, the highest HDI\_2016 is 0.949, representing 2.7 times the lowest. The new method then increases international inequality of development levels. The new international inequality is more realistic, close to the one associated

with GDP per capita, as we see on the table below.

**Table 2.** Comparison of international inequality related to HDI and HDI variables

Indicators	HDI	New HDI	Life Expectancy at Birth	Expected Years of Schooling	Mean Years of Schooling	GNI/capita
Maximum	0.949	0.989	84.163	20.433	13.370	129 915.601
Minimum	0.352	0.008	48.943	4.872	1.442	587.474
Max - Min	0.597	0.982	35.220	15.561	11.928	129 328.127
Mean	0.699	0.316	71.353	12.983	8.372	17 313.866
Standard deviation	0.1551	0.3833	8.2966	2.897	3.0970	19069.312
Relative standard deviation	0.2219	1.212	0.1163	0.22315	0.3699	1.241389

*Source: Our results from the UNDP's HDI data*

The apparent low relative standard deviation of life expectancy does not take into account the penibility of life. In poor countries, people can live a relative long life, but they certainly live a penible life. This relative standard deviation would have been higher if it took into account the quality of life. This is true for education. If the quality of education was taken into consideration, the relative standard deviation would have been higher for expected years of schooling and for the mean years of schooling.

The UNDP's HDI 2016 distribution shows a relative standard deviation equal to 0.1551; lower than the one related to the new-HDI 2016 distribution which is 1.212; while the one associated to GNI per capita is 1.241. The inequality of the new\_HDI is close to the world reality. UNDP abnormally and unrealistically reduces inequality between rich and poor countries, while in the reality there is a huge difference of quality of life between developed and underdeveloped nations.

## CONCLUSION

We have proposed a new methodology of calculating material welfare from the GNI per capita. This method takes into consideration the fact that GNI per capita is a macroeconomic variable and, as such,

faces increasing marginal utility. This is supported by the fact that in rich countries, rich people pay more taxes, so their governments are strong and rich, and can produce adequate social services and collective infrastructure that enable low-income owners to live conveniently; whereas in poor countries, poor governments provide poor social services and poor collective infrastructures that reduce material welfare of high revenue owners.

We have applied this method on HDR\_2016 database and computed a new HDI\_1996 for all countries. Two important observations can be made. First, the new HDI\_2016 ranges from 0.008 (Central African Republic) to 0.989 (Norway); while the HDI\_2016 ranges from 0.352 (Central African Republic) to 0.949 (Norway). The inequality of new-HDI\_2016 is more important and more realistic than the inequality of HDI\_2016. It can then be considered to be closer to the one associated to GNI per capita than the one obtained under diminishing returns of GNI per capita. This is an answer to the problem raised by McGillivray and Pillarisetti (2004). Secondly, there is a modification of countries ranking. This modification is important for some countries, especially for average HDI countries, and not important for other countries, positive for some countries and negative for some others. Some African countries, rich in natural resources, have registered important positive rank modification: Gabon have moved from the 109<sup>th</sup> to the 63<sup>rd</sup> position, Equatorial Guinea from the 135<sup>th</sup> to the 62<sup>nd</sup> position, Botswana from the 108<sup>th</sup> to the 75<sup>th</sup> position. Other countries have registered important negative variation of their rank: Ukraine from the 84<sup>th</sup> to the 109<sup>th</sup> position, Armenia from the 84<sup>th</sup> to the 103<sup>rd</sup> position, Cuba from the 68<sup>th</sup> to the 101<sup>st</sup> position.
