ABSTRACT: *Pseudomonas aeruginosa* is a frequent nosocomial pathogen that causes severe disease in many clinical and community settings. The objective of this paper was to isolate *Pseudomonas aeruginosa* from clinical samples and to investigate the occurrence of metallo β- lactamase enzyme production by collecting 145 males and 90 females' human clinical specimens from five selected health institutions within Kwara state, Nigeria. The samples were cultured immediately using standard microbiological procedures. Multiple drug resistance patterns of the bacteria to different antibiotics were determined using the Bauer Kirby disc diffusion technique. Metallo – β lactamase production was determined using E – test strip. Data were subjected to descriptive statistics using Statistical Package for Social Sciences (SPSS) software. A total of 145 isolates were identified as *Pseudomonas aeruginosa* from the clinical samples.Thirty were positive for metallo β lactamase production; 11 (8 %) males and 19 (13 %) females. Absolute resistance to ceftazidime (100 %), gentamicin (100 %), ceftriaxone (100 %) were observed while low resistance to ciprofloxacin (12.4 %), piperacillin (6.9 %) and imipenem (6.9 %). All isolates were sensitive to colistin. This study had demonstrated that there is a high occurrence of metallo β lactamase enzyme producing and antibiotic-resistant strains of *P. aeruginosa* in clinical specimens from the studied area. Necessary measures must be implemented to stop the problems of this antibiotic resistance.

Keywords: Metalo-β-lactamase enzyme, *P. aeruginosa*, clinical samples, antibiotic-resistant genes.

Pseudomonas aeruginosa is widespread in natural environments and considered an opportunistic secondary pathogen for humans that is capable of causing a major nosocomial infections and broad spectrum of infections such as urinary tract, burn, respiratory tract, meningitis, chronic otitis media and otitis externa, pseudomonal endocarditis, septicaemia, etc. (Singh *et al.*, 2006; Yang *et al.*, 2011). It is also implicated in 16 % of nosocomial pneumonia, 12 % in urinary tract infections, 8% in surgical infections, and 10% in bloodstream infections. Otherwise, there is increasing evidence implication of the species in foodborne infections (Vitkauskienė *et al.*, 2010). *Pseudomonas aeruginosa* is not only but one of the main causes of healthcare-associated infections mostly common among hospitalized patients (Kyaw *et al.*, 2015). Healthcare-associated infections predominantly lead to pneumonia, urinary tract infections as well as, skin and soft-tissue infections. Occasionally, *P. aeruginosa* can colonise human body sites, with a preference for moist areas, such as the perineum, axilla, ear, nasal mucosa and throat, stool as well as subungual areas of the hands (Hilmar *et al.*, 2018). The prevalence of colonisation in healthy individuals is usually low, higher colonisation rates can be encountered following hospitalisation, especially among patients treated with broad-spectrum antibiotics. A multidrug resistant (MDR) *P. aeruginosa* phenotype is defined as a bacterium which is resistant to three or more anti-pseudomonal anti-microbial classes; carbapenems, fluoroquinolones, penicillins / cephalosporins and aminoglycosides (Magiorakos *et al.*, 2012). The mechanism of resistance in MDR *P. aeruginosa* is possibly through the production of several enzymes that inactivate beta-lactams and carbapenems such as extended spectrum beta lactamases (ESBLs) and metallo-β-lactamases (MBLs) (Vahdani *et al.*, 2012). Therefore, this study was aimed at isolating *Pseudomonas aeruginosa* from clinical samples and investigating the occurrence of metallo β- lactamase enzyme among them.

MATERIALS AND METHODS

One hundred and forty five clinical specimens of *Pseudomonas aeruginosa* isolates were isolated from urine, wound, sputum, blood and indwelling medical devices. Specimens were collected from primary, secondary, tertiary hospitals, and private diagnostic centres across Kwara state, Nigeria

Ethical consideration: Ethical approval was obtained from the Ethical Review Committee (ERC) of Kwara State Ministry of Health, Ilorin.

Clinical samples were collected from different hospital wards of University of Ilorin Teaching Hospital, the samples include: urine, sputum, catheter tip, cornea scraping, blood, wound swab and ear swab. They were

processed, cultured and the bacteria identified at the Medical Microbiology and Parasitology laboratory unit of University of Ilorin Teaching Hospital (UITH) Ilorin.

Innoculation and Incubation: The clinical samples were collected into a transport media (Nutrient broth) and it was further transported into the laboratory. The culture was incubated overnight at 42 °C for 24 hours. The overnight broth culture was futher sub-cultured on MacConkey agar and Blood Agar. Incubation of the cultured plates was done under aerobic conditions. The bacterial growth was observed for colonies morphologically resembling *Pseudomonas aeruginosa* on MacConkey agar in aerobic conditions. Colonies morphologically resembling *P. aeruginosa* were subjected to further characterization.

Confirmation of Pseudomonas aeruginosa strains: Production of pigments such as pyocyanin was tested by growing the isolates on cetrimide agar for confirmation results obtained were compared with specifications in Bergey's Manual of Systematic Bacteriology.

Antimicrobial susceptibility testing: Antibiotic susceptibility testing was performed using modified Kirby-Bauer disc diffusion method following guidelines of Clinical and Laboratory Standards Institute (CLSI, 2015).

Metalo-β-lactamase enzyme *detection:* The inoculum of *Pseudomonas aeruginosa* was prepared (CLSI, 2015). Each isolates of *P. aeruginosa* was inoculated on a separate Mueller Hinton plate. MBL E-test strips containing concentration gradient (1 - 64 µg/ml) of imipenem (IP) on one end of the strip and imipenem overlaid with a constant concentration of EDTA (IPI) on the other end of the strip were placed onto the plate and incubated at 42°C aerobically for 18-24 hours as shown in plates 3.7a and 3.7b. Negative control was set along with the test using *P. aeruginosa* ATCC 27853. A reduction in the Imipenem minimum inhibitory concentration (MIC) in the presence of EDTA of greater than or equal to eight-fold (IP/IPI ≥ 8) indicated MBL positivity.

RESULTS AND DISCUSSION

Out of the 145 *P. aeruginosa* isolates examined. Table 1 shows the distribution of *P. aeruginosa* according to the sources of infection which include urine, sputum, cornea scrapping, wound swab, ear swab, catheter tip and vaginal swab. *P. aeruginosa* isolates (32.5 %) were mostly isolated from ear infection, which was followed by wound infection. The lowest percentage of isolates was found in catheter tip. 30 (21 %) were MBL producing *P. aeruginosa* while 115 (79 %) were negative for MBL production. Of the 30 MBL positive isolates the male population account for about 11 (8 %) while the female population account for 19 (13 %) while 115 isolates were found to be negative for MBL production in which the female population accounts for 63 (43 %) while 52 (36 %) was found in the male population this is shown in Table 2. During the study period, MBL positive isolates were found to be resistant to ceftriaxone and ceftazidime (100 %) while a relative decrease in the susceptibility pattern of the MBL negative isolates to ceftriaxone and ceftazidime with 55 isolates (37.9 %) susceptible and 90 isolates (62.1 %) respectively as presented in Table 3. Of the 30 MBL positive isolates, 18 (12.4 %), 5 (3.4 %) were susceptible to ciprofloxacin and gentamicin? while 12 (8.3 %), 15 (10.3 %) were resistant for ciprofloxacin and gentamicin, respectively. In addition, out of the 115 MBL negative isolates, 67 (46.2 %) and 100 (69.0 %) were susceptible to ciprofloxacin and gentamicin respectively.

Table 1: Distribution of *P. aeruginosa* according to the sources of infection

Sources of *Pseudomonas aeruginosa*	**Frequency (%)**
Urine	10 (14.5)
Sputum	15 (21.8)
Cornea Scrapping	8 (11.6)
Wound Swab	36 (52.2)
Ear swab	40 (58)
Catheter tip	5 (7.25)
Vaginal Swab	32 (46.4)
Total	145

Table 2: The gender distribution of patients infected with *P. aeruginosa*.

Gender	**MBL Producers (%)**	**Non MBL Producer (%)**
Male	11 (8)	52 (35.9)
Female	19 (13)	63 (47.6)
Total	30 (21)	115 (79)

Plate 1 displays the photograph of MBL positive *P. aeruginosa* showing a phantom zone which is characteristic of MBL producers while plate 2 displays the photograph of MBL positive *P. aeruginosa* showing IP/IPI≥8

Plate 1: Photograph of MBL positive *P. aeruginosa* showing a phantom zone which is characteristic MBL producers.

Table 3: Frequency of Antibiotics susceptibility pattern of MBL and Non MBL *P. aeruginosa.*

Antibiotics Used	Total number of Isolates N=145	MBL Producers N=30 (%)	Non MBL Producers 115 (%)	X^2	p-value

Pseudomonas aeruginosa is commonly implicated as a cause of health care acquired infections with high mortality rates (Lambert *et al.,* 2011). The high rate of microbial resistance to the cephalosporins as observed in this study is a cause for concern as because many clinicians fall back on them for the treatment of Gram-negative pathogens in the face of multi-drug resistance. The high incidence of the isolates resistant to the cephalosporins and quinolones may be attributed to cross-resistance to the class occasioned by high non-prescription use of ciprofloxacin in the area as well as possible drug faking. The results of the antibiotic resistance profile of the isolates to beta-lactam antibiotics showed increased beta-lactamase enzyme production among the isolates. Many of the MBL producing isolates were resistant to ceftriaxone (100 %), ceftazidime and ciprofloxacin (100 %) respectively, Anupurba *et al.* (2006) reported the isolation of cephalosporin resistant *P. aeruginosa* among in-patients and outpatient clinics, made a similar observation. In this study the prevalence of MBL producing *P.aeruginosa* was found to be 21 %. This result was lower than 36.07 % reported by Sasirekha *et al.,* 2010 and higher than the prevalence reported in Lagos (Aibinu *et al.,* 2007), and in Belgium (Berges *et al.,* 2007) where the prevalence was 4.1 % and 4.4 %, respectively. It is also higher than the prevalence of 10.0% and 14.0% obtained in Enugu, south east, Nigeria (Ejikwegu *et al.,* 2014) and India (Hemalatha *et al.,* 2005), respectively.

The prevalence of MBL producing *P. aeruginosa* in male to female in this study is 7.59 % as compare to 13.1 %. This is in line with the study by Mojtaba *et al.* (2014). Females were more affected than males (53 % to 47 %). This is in contrast with the study carried out by Sandhya and Swathi, (2015) reported 7:1. Some studies shows that more males are infected with *P. aeruginosa* than female (Sandhya and Swathi, 2015)

The highest number of susceptibility of *P. aeruginosa* isolates was recorded for colistin (77.2 %) followed by imipenem (65.5 %). This result for colistin contradicts studies from Nwankwo and Shaibu (2010) who reported 78.9 % susceptibility of *P. aeruginosa* but corroborate result of Aibinu *et al.* (2007) and Olayinka *et al.* (2009) who reported 95.6 % and 94.6 % respectively. They explained that the duration of the hospital stay was directly proportional to a higher prevalence of the infection. Aminoglycosides (streptomycin and gentamicin), on the average, had less activity and showed more microbial resistance profile compared to β-lactam drugs and carbapenem. The reason for this high resistance to the aminoglycosides could be as a result of indiscriminate use of gentamicin in the area. The drug though a prescription only medicine is purchased as over-the-counter in the open markets in the community and is commonly used by unqualified personnel in the

treatment of "infections". Several studies show that gentamicin and streptomycin are effective against *Pseudomonas* species and *E. coli*, but if misused, the organisms may also develop resistance to them. This research findings is similar to that of Sasirekha *et al.* (2010) where they recorded 82.1 % susceptibility of the isolates to gentamicin and 41.8 % to streptomycin probably although they worked on clinical isolates generally and not on ESBL producers alone.

The high resistance profile of the isolates in this study is a reflection of the high incidence of MBL and ESBL isolates observed. *P. aeruginosa*, much like *Mycobacterium tuberculosis* is intrinsically resistance to several antimicrobial classes and therefore poses considerable limitation in the range of antibiotic options for treating infections caused by them. These increase further the risk for emergence of resistant strains. Bacteria usually encode multiple antibiotic resistance genes.

MBL producers were found more in females than males, this may be due to the fact that women are relatively weaker and more sensitive. The results of susceptibility pattern of *P. aeruginosa* isolates to antimicrobial agents in this study showed that the 145 *P. aeruginosa* strains tested against seven antimicrobial agents; shows that all the MBL strains of the isolates were resistant ceftazidime, and gentamicin recording 100%. Piperacillin and imipenem have the same sensitivity pattern for MBL while Colistin has the highest percentage of sensitivity with few isolates resistant to the drugs this is because it is an amphiphatic drug. That is why it is always used as a last resort to multi drug resistance strains.

The result of this study showed that there is an increase in resistance to the quinolones by strains of *P. aeruginosa*. In previous studies by Oduyebo *et al.* (1997) and Kesah *et al.*(1999) in this environment, *P. aeruginosa* strains were found to be highly susceptible to the quinolones (96%); but from this study, our data shows increase in resistance to this family of antibacterial agents by the current clinical strains of *P. aeruginosa*. Ofloxacin was observed to have the highest activity (41%) and was closely followed by ciprofloxacin (39%). This result implies that quinolones alone, cannot be depended upon as an antipseudomonal antimicrobial in this environment. They will have to be used in combination or replaced with another antimicrobial preferably. The activities of carbapenems, ceftazidime, piperacillin/tazobactam and amikacin against *P. aeruginosa* strains is still high and they can be considered as therapeutic options available for *P. aeruginosa* infection treatment in this region.

Conclusion: Metallolo-β-lactamase producing *P. aeruginosa* strains were found in Kwara State which is the North central Nigeria and result of this work shows the presence of this enzyme in the pathogen, *P. aeruginosa* in environment which may also confer resistance on the organism.
