Abstract

In this study, the effects of sea-buckthorn (*Hippophae rhamnoides* L.) leaves (SL) on the biochemical parameters and metabolomic profiling in Altay lamb (*Ovis aries*) were observed. Sixty six-month-old male Altay lambs (body weight 28.0 ± 3.5 kg) were randomly assigned to four groups (n=15). The experimental groups were named as CON, 2.5%, 5.0% and 7.5%. The group CON, contained animals fed with a basal diet. Animals of the other groups were fed a treatment diet consisting of 2.5% (Group 2.5%), 5.0% (Group 5.0%) and 7.5% (Group 7.5%) SL. The experimental period lasted 56 days. The results showed that the average daily gain (ADG) and average daily feed intake (ADFI) increased with the increase in the levels of dietary SL. Dietary SL showed a direct relationship with total protein (TP), albumin, globulin and total cholesterol (TC) content of the experimental animals. However, an indirect relationship was observed between dietary SL and the concentration of urea nitrogen (UN). The concentrations of glucose, high-density lipoprotein cholesterol (HDL-C) and low-density lipoprotein cholesterol (LDL-C) showed quadratic change. Additional changes occurred in the endogenous metabolites involving multiple pathways. The pathways were tricarboxylic acid (TCA) cycle, the metabolism of protein and amino acid and the metabolism of fatty acid and steroid. The changes in metabolites primarily revealed an increase in amino acids and carbohydrates and a decrease in lipid metabolites. These findings provide a comprehensive insight into the effects of the metabolic aspects of sea-buckthorn leaves on Altay lambs. In addition, the present research results provide a better understanding to the development and utilization of sea-buckthorn as a healthy additive for small ruminant production.

Introduction

Sea-buckthorn (*Hippophae rhamnoides* L., Fam. Elaeagnaceae), is a hardy branched and thorny nitrogen-fixing deciduous shrub (Yildiz *et al.*, 2012). The plant is native to and widespread throughout the north-western Europe and Central Asia to the Altai Mountains. It is further distributed in the western and northern China, and the northern Himalayas (Heinz *et al.*, 1998; Zhao *et al.*, 2017). All parts of the plant are considered rich in biologically active substances. Those are flavonoids, carotenoids, steroids (ergosterol, stigmasterol, lanosterols, and amyriols), vitamins C, E and K, fatty acid, and some essential amino acids (Rousi *et al.*, 1971; Beveridge *et al.*, 1999; Srivastava *et al.*, 2013; Guliyev *et al.*, 2004). These compounds have beneficial effects on human health, such as anti-atherogenic, antioxidant, anti-cancer, and anti-bacterial effects (Suomela *et al.*, 2006; Yuan *et al.*, 2016; Wang *et al.*, 2018).

Sea-buckthorn leaves are rich in nutrients and bioactive substances. It is used widely throughout the world because of its high medicinal and nutritional properties (Li *et al.*, 2007). In The People's Republic of China, sea-buckthorn covers an area of more than 500,000 ha (Chen *et al.*, 2010). The supplementation (0.1%) of sea-buckthorn extraction in the diets of piglets has been found to reduce fat deposition (Liu *et al.*, 2008). However, little information is known about the effects of sea-buckthorn leaves on small ruminants.

Metabolomics is a powerful approach to delineating the global metabolic profiling of living organisms. It also acts as the basis of capturing the subtle metabolic alterations associated with physiological and pathological stimulations. It has been widely used in drug toxicity detection (Oresic *et al.*, 2009), disease diagnosis and animal model research (Gupta *et al.*, 2005). Metabolomics also contributes in feed nutrition and livestock production (Nie *et al.*, 2015; Zhang *et al.*, 2017). Recent publications on metabolomics have focused on the relationship between metabolite changes, overall biology, and biomarkers (Nicholson *et al.*, 1999). Wood *et al.* (2010) reported that dietary docosahexaenoic acid (DHA) supplementation altered the selected constituents of the physiological brain and the plasma endocannabinoid metabolomes. DHA also had produced effects on endocannabinoid-related lipid species, indices of psychobehavioral and physical health.

Altay lamb (*Ovis aries*) is an ancient shag lamb breed that originated in the Altay region of Xinjiang, China. It is an important source of meat which provides nutrition and generates income to the local people.

The authors, therefore, conducted this study to analyse the performance and serum metabolic alterations caused by sea-buckthorn leaves in Altay lamb. This will provide a theoretical basis for the development and utilization of sea-buckthorn leaves as a healthy additive for small ruminant production.

Materials and Methods

For the present research, leaves of sea-buckthorn (SL) were collected in August during the fruiting period from Qinghe County (Xinjiang, China). The SL samples were dried under natural conditions for six days until the moisture content was less than 25%. The diameters of the stems were less than 1 cm. After drying, the SL were thoroughly mixed with other dietary components in a Total mixed ration mixer and fed to the experimental lambs. The chemical compositions of the SL were analysed for dry matter (DM), crude protein, ether extract, crude ash, neutral detergent fibre, acid detergent fibres, calcium, and phosphorus (AOAC, 2000). Gross energy content of the SL was determined using a bomb calorimeter Parr® 6200 (Table 1).

Table 1 Chemical composition of sea-buckthorn leaves

Items	Content
Dry matter	92.62
Crude protein, % of DM	11.73
Ether extract, % of DM	5.05
Crude ash, % of DM	9.14
Neutral detergent fibre, % of DM	29.94
Acid detergent fibres, % of DM	20.34
Calcium, % of DM	0.41
Phosphorus, % of DM	0.18
Gross energy, MJ/Kg	15.70

Sixty six-month-old male Altay lambs (body weight 28.0 ± 3.5 kg) were randomly assigned to four groups (3 replicates of 5 lambs in each group). For the experimental purpose, the groups were named CON (control i.e., 0%), 2.5%, 5.0% and 7.5%. The group CON was fed with 100% wheat straw i.e., the basal diet. While the lambs of groups 2.5%, 5.0% and 7.5% received a feed containing 2.5, 5.0 and 7.5% replacement of the basal diet by SL, respectively. The experimental period lasted for 56 days including seven days as adaptation phase. The diets were formulated according to the nutrient recommendations for small ruminants (NRC 2007) (Table 2). The lambs were housed at moderate temperature ($15.78 \pm 0.61^\circ\text{C}$) and humidity ($60.12 \pm 1.80\%$). They had free access to feed and drink water in the rearing period. The animal care and use protocols were approved by the Animal Welfare Committee of Shihezi University.

During the experiment, the refused feed was weighed daily for each group. The lambs were weighed individually at the beginning and end of the trial. At the end of the experiment, six lambs per group whose weight was close to the average weight of the group were randomly selected for blood collection. Blood samples (5 mL) were collected from the jugular veins after 12 hours' food deprivation. All blood samples were centrifuged at $2700 \times g$ at 4°C for 15 min to isolate the serum, which was separated into sterilized

tubes and stored at -80°C until further analysis.

¹CON: 2.5%, 5.0%, and 7.5% mean that supplementation of SL was 0%, 2.5%, 5.0%, and 7.5% and replaced the equivalent amounts of wheat straw, respectively

²Vitamin A: 15 000 IU, vitamin D: 5 000 IU, vitamin E: 50 mg, iron:90 mg, copper: 12 mg, manganese: 50 mg, zinc: 110 mg, selenium: 0.3 mg, cobalt: 0.5 mg (g/kg diet)

³Metabolizable energy = [(digestible organic matter, g/kg DM)/1000] × 18.5 × 0.81, according to ARC (1990). The nutrient levels are actual measured values, except ME value, which was calculated.

Total protein (TP), albumin, globulin, urea nitrogen (UN), glucose, creatinine, total cholesterol (TC), triglycerides (TG), high-density lipoprotein cholesterol (HDL-C), and low-density lipoprotein cholesterol (LDL-C) were assayed using automatic biochemical analyser kits by Abbott AerosetC4000 (Abbott Laboratories, Chicago, USA).

The serum samples were thawed (50 µL) at room temperature and dried in GC (gas chromatograph) vials in moderate nitrogen gas. Methoxyamine (30 µL) in pyridine (20 mg/mL) was added and mixed vigorously for 30 seconds with the help of a vortex mixer. Methoxyamination reaction was performed at 37°C for 90 min, and then 30 µL of BSTFA with 1% TMCS was added to the sample as a catalyst. Finally, the solution was shaken for 60 min at 70°C, and then cooled for 30 min at room temperature for gas chromatography-mass spectrometry (GC-MS) analysis.

All samples (1 µL) were analysed with an Agilent 7890A/5975C GC/MS system with a capillary column (HP-5MS, 30 m × 0.25 mm × 0.25 µm) (Agilent Technologies, Shanghai, China). Helium gas was used as the carrier gas through the column at a flow rate of 1 mL/min. The injector, MS quadrupole, and ion source temperature were 280°C, 150°C and 230°C, respectively. The initial temperature was kept at 80°C for 2 min, and then raised to 320°C at a speed of 10°C per min, which was maintained for 6 min. The masses were

acquired in full scan mode from mass-to-charge (m/z) ratio of 50:500.

All MS data were analysed by AMDIS (automated mass spectral deconvolution and identification system) software for peak deconvolution, and NIST mass spectral library was used for peak identification.

The data were analysed using the PROC MIXED procedure of SAS (SAS Institute Inc., Cary, NC). The model included treatment and block as fixed effects. The results were reported as least squares means. Contrasts were used to test the linear, quadratic and cubic changes as affected, because of the increasing amount of dietary SL. Diagnostics were examined for the homogeneity and normality of the residuals and were not of concern for the variables studied here. Significant differences were declared at $P < 0.05$, and the trends were reported at $0.05 \leq P < 0.10$. Principal component analysis (PCA) and partial least squares-discriminant analysis (PLS-DA) were performed via Simca-P 11.5 software (Umetrics, AB, Sweden). The variable significance in the projection (VIP) values ($VIP > 1.0$) and t -test ($P < 0.05$) were both employed to find differentially expressed metabolites.

Results

The effect of SL on growth performance of Altay lamb is presented in Table 3. Neither the initial nor the final body weight of lamb in this study was influenced by the treatments. ADG increased linearly ($P < 0.05$) with increasing SL levels. The values were compared with those from CON. The ADG in lambs fed with 5.0% SL and 7.5% SL increased ($P < 0.05$) by 8.16% and 7.85%, respectively. However, those that were fed 2.5% SL did not differ in their ADG compared with the CON group. ADFI was linearly increased ($P < 0.01$) with rising SL levels. The ADFI was higher in the 5.0% SL than in CON ($P < 0.05$). Additionally, no difference was observed in feed conversion ratio (FCR) among treatments.

Table 3 Effect of sea-buckthorn leaves on production performance of Altay lamb

Items	Treatments ¹				SEM	P-value			
	CON	2.5%	5.0%	7.5%		Treatment	Linear	Quadratic	Cubic

¹CON, 2.5%, 5.0%, and 7.5% mean that supplementation of SL was 0%, 2.5%, 5.0%, and 7.5% replaced the equivalent amounts of wheat straw, respectively

^{a, b}Means within the same row with different lowercase letters indicate significant difference ($P < 0.05$)

With the increasing amount of dietary SL, TP, albumin, globulin and TC increased linearly ($P < 0.05$) (Table 4). The concentration of glucose, HDL-C and LDL-C increased in a quadratic way ($P < 0.05$) with increasing dietary SL levels (Table 4). However, dietary treatments had no effect on the concentrations of creatinine and TG in the blood ($P > 0.05$).

PCA models with good clusters of both the control and SL groups and no strong outliers were observed (Figure 1). These presented apparent groupings, with only partial overlapping between the control and SL data. To obtain improved model transparency and interpretability, PLS-DA and chemometric analysis were performed. All these helped to screen differential variables. These showed a clear separation between the CON and SL groups without any overlap (Figure 1). So, one predictive component and two orthogonal components with satisfactory modelling and predictive abilities $R^2(X) = 0.392$, $R^2(Y) = 0.558$, and $Q^2(\text{cum}) = 0.189$ were produced. On the basis of the overall analyses, the results indicated that the predictive capabilities of the PLS-DA models of the GC-MS data were reliable.

GC-MS analyses identified a total of 17 metabolic components mainly from amino acid, carbohydrate and lipid super classes (Table 5). The metabolic alterations between the CON and SL groups have been listed in Table 5. SL group-induced alterations in the amino acid-related metabolites were valine, alanine and glycine. Concentrations of these metabolites were increased in SL groups compared with the CON ($P < 0.05$). Valine and alanine were increased in SL groups compared with the CON group ($P < 0.05$), and glycine was decreased ($P < 0.05$). From lipids, compared with CON, β -Hydroxybutyric acid, palmitic acid, oleic acid, oleic

acid amide, octadecanamide, and cholesterol were decreased but linoleic acid and stearic acid were increased ($P < 0.05$).

Various metabolites between CON and SL groups were subjected to MetaboAnalyst 3.0 software, which revealed their association with the metabolic pathways. It was found that differential metabolites between CON and 2.5% SL group were involved in the metabolisms of glycerolipid, butanoate, alanine, aspartate and glutamate, taurine and hypotaurine, linoleic acid, fatty acid, primary bile acid, tricarboxylic acid and steroid hormone biosyntheses (Figure 2). Differential metabolites between CON and 5.0% SL and 7.5% SL that are responsible for the pathways were presented in Figure 2. Moreover, nine pathways, including the metabolisms of glycerolipid, butanoate, alanine, aspartate and glutamate, taurine and hypotaurine, linoleic acid, and fatty acid, and in the biosyntheses of primary bile acid and steroid hormone were shared in the three comparisons. These pathways were filtered out by false discovery rate less than 0.05 having an impact more than 0.

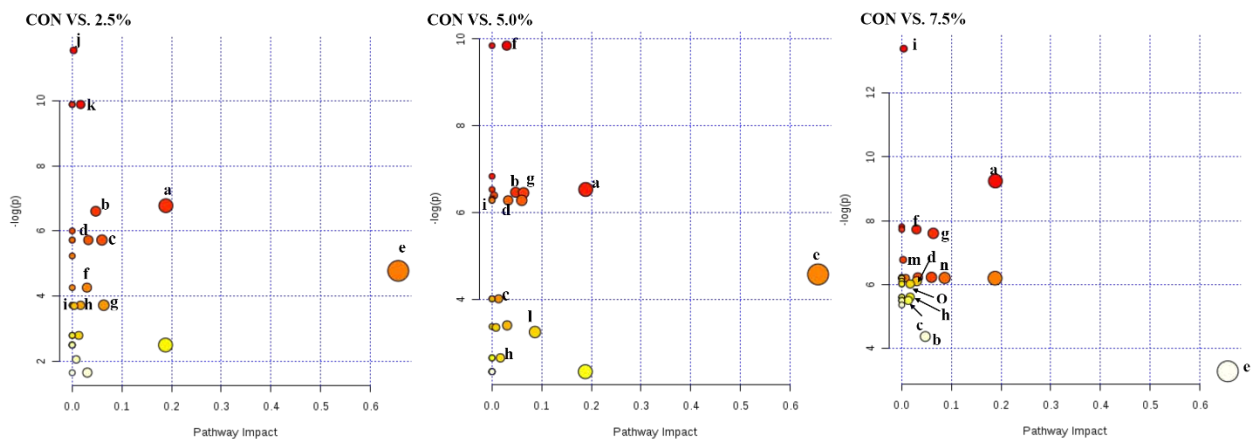

Figure 2 Pathway analysis of differential metabolites between four groups with MetaboAnalyst.

The x-axis represents the pathway impact, and y-axis represents the pathway enrichment. Larger sizes and darker colours represent higher pathway enrichment and higher pathway impact values, respectively.

CON, 2.5%, 5.0%, and 7.5% mean that supplementation of SL was 0%, 2.5%, 5.0%, and 7.5% replaced the equivalent amounts of wheat straw, respectively.

CON versus 2.5% = differential metabolites between CON and 2.5% treatment. CON versus 5.0% = differential metabolites between CON and 5.0%. CON versus 7.5% = differential metabolites between CON and 7.5%.

Discussion

To improve the digestibility of food and food intake, natural food additives are commonly used for raising animals (Fang *et al.*, 2008). Studies have shown that plant extracts can improve food intake and food digestibility in ruminants (Prakash *et al.*, 2010; Velagapudi *et al.*, 2010). The leaf and fruit of sea-buckthorn can improve the average daily gain and feed conversion in monogastric animals (Zhao *et al.*, 2012). Sea-buckthorn leaves are rich in flavonoids, which have been found to increase ruminant food intake and digestibility. This might be due to the fact that the extracts can improve the palatability of the diet, while changing rumen microflora can help regulate intestinal flora (Windisch *et al.*, 2008; Xie *et al.*, 2010). In the present study, a higher ADG was observed in the SL-supplemented diets compared with the CON. Presumably, the high doses of SL increased feed intake and indicated that SL improved growth and feed conversion rate.

The function of tissues and organs and the nutritional status of bodies are reflected in serum biochemical indicators (Williams *et al.*, 1997). This concept has helped to establish that SL improved growth performance in the experimental animals. Serum TP is made up of albumin and globulin. High TP content enhances metabolism and immunity, and promotes health and growth in animals. The concentration of serum TP is believed to be associated with the protein supply and growth performance of animals. The serum UN content reflects the balance between the metabolism of protein and amino acid, and decreases if the balance of amino acid is good in animals (Baumhoer *et al.*, 2011). In this study, increased levels of sea-buckthorn leaves showed a linear increase in TP ($P < 0.01$), and UN was lower than in the control group. This

indicated that SL promotes protein biosynthesis and improves growth and feed conversion rates (Velagapudi *et al.*, 2010). Glucose is the main source of energy, which is positively correlated with the growth rate. The current results showed that the concentration of glucose in SL treated animals was increased. It further indicated that SL could promote energy metabolism and weight gain. Creatinine is a small molecular substance that can be filtered through the glomerulus and is rarely absorbed in the renal tubules. Thus the creatinine produced in the body every day, is almost completely excreted with the urine, and is generally not affected by the amount of urine. When renal insufficiency occurs, creatinine accumulates in the body and becomes a harmful toxin. This affects the metabolism of digestive and respiratory systems. In the present study, no difference was found in plasma concentration of creatinine among treatments. This finding indicates that SL had no adverse effects on renal function. According to Ali *et al.* (2012), sea-buckthorn does not produce toxicity, even at the highest dose. In the present study, the concentration of TC decreased linearly with increasing level of SL. A similar TC decreasing effect was found by Pichiah *et al.* (2012). This might be due to the dynamic balance of components in the serum. The concentration of cholesterol increased with TP concentration. In common, cholesterol is transported to the tissues in the form of LDL-C in the blood. In the SL groups, increased LDL-C indicates that SL promotes cholesterol metabolism, thereby regulating lipid metabolism.

Metabolomics provides a powerful approach to delineating the global metabolic profiling of living organisms (Patti *et al.*, 2012). It can also comprehensively reveal the change rule and related mechanism of the biosystem that are affected by exogenous substances (Cheng *et al.*, 2017). In the present study, comprehensive analyses were performed of the changes in the metabolites in serum metabolic profiling. This helped to reveal alterations in the body's metabolism when lambs were on the SL diet.

The present study not only detected the different metabolites between the CON and SL diets, but also pinpointed the pathways where those metabolites were active. The metabolites involve a variety of metabolic pathways, including the TCA, steroid hormone biosynthesis, and metabolism of amino acids and fatty acids. All these could be regarded as the most important pathways associated with the metabolic changes in the lambs fed SL diets. So, comprehensive and essential metabolic changes were established in the lambs fed with SL diets.

SL supplementation in the diets of the experimental lambs increased the content of fumaric acid. This acid has been considered as a critical intermediary metabolite in the TCA cycle. Therefore, it implied that supplementation of SL caused a change in energy metabolism. In this study, the concentrations of alanine, glycine, and valine were increased with the addition of SL. In the process, glycogenic amino acid, alanine and glycine can be metabolized to pyruvate, and valine can be converted into succinate coenzyme A. All these enter into the TCA cycle and gluconeogenesis to produce energy (Pilviet *et al.*, 2008). Moreover, valine is one of the branched-chain amino acids (BCAA), and its increasing evidenced that BCAAs play important roles in regulating the lipid metabolism (Ying *et al.*, 2012; Nishimura *et al.*, 2010; Xiao *et al.*, 2016). In this study, the concentration of glycine, as a critical metabolite in the γ -glutamyl cycle, increased with the addition of SL. This suggested that the γ -glutamyl cycle was enhanced and oxidative stress damage was reduced (Zhang *et al.*, 2012). Similarly, Du *et al.* (2017) confirmed that sea-buckthorn paste has potent antioxidant activities *in vitro* and *in vivo*. The phenomenon might have delayed the kidney damage caused by oxygen free radicals. A protection towards these were given by adjusting the kidney antioxidant enzymes Na^+ - K^+ -adenosine triphosphatase, and lipid peroxide products (e.g. malondialdehyde and nitric oxide). Hence, the increased glycine can improve the antioxidant ability of the body and is beneficial to the health of Altay lamb. The glucose level was increased in metabolomic analyses of serum samples in the SL groups compared with CON. The normal source of energy in the body is supplied by glucose oxidation through aerobic respiration (Sun *et al.*, 2017). This result reflected that the supplementation of SL has an effect on the energy metabolism of the Altay lamb.

On the one hand, saturated fatty acids bring beneficial health effects through reducing plasma TG, causing a moderate reduction in blood pressure and regulating cholesterol metabolism (Ruxton *et al.*, 2010; Sutter *et al.*, 2012). On the other hand, linoleic acid is an unsaturated fatty acid (UFA) and one of the two essential fatty acids. In the present research, the level of linoleic acid was increased in SL groups, compared with the CON. So, it suggests that, Altay lamb cannot synthesize it from other food components.

Conclusion

The daily gain and serum content of TP, TC, and LDL-C increased gradually with the supplementation of SL, while the content of UN was reduced. The high content of SL increased the HDL-C concentration in Altay lamb. The dietary supplementation of SL altered multiple metabolic pathways, including the TCA cycle and the metabolism of amino acids, fatty acids, and steroids. This study has allowed a better understanding of the effects of SL on Altay lamb and provided a theoretical basis for the development and utilization of sea-buckthorn leaves as an additive for ruminant production. Further studies are warranted to better define the

effects of sea-buckthorn leaves in anti-oxidation performance and lipid metabolism of ruminants.

Acknowledgements

This research was partially supported by grant of the National Key R&D Program of China (2017YFD0500500 and 2018YFD0502100) and National Modern Mutton Sheep Industry technology system (nycytx-39).

Authors' Contributions

WJZ, CYG, and CXN contributed to the idea, design and execution of the study. LYF and NJL contributed equally to the write-up of the final manuscript. YFL, and SZT assisted in all lamb procedures for the experiment. GTH, WQW, and WXG performed the samples analysis. NJL and LYF were responsible for the statistical analysis.

Conflict of Interest Declaration

The authors declare that there was no conflict of interest.
